(57) **ABSTRACT**

Third party data embedding may be provided. Data associated with a third party provider may be saved in a native application save file. If a save file opened by the application is determined to comprise third party data, the application may determine whether an appropriate data provider is available. The application may connect to the data provider and provide on-demand, asynchronous access to the third party data upon request from a user.

FIG. 4

## 1

**EMBEDDING AND RETRIEVING DATA IN  
AN APPLICATION FILE FORMAT****CROSS REFERENCE TO RELATED  
APPLICATIONS**

The present application is a continuation of U.S. patent application Ser. No. 12/605,126, filed Oct. 23, 2009, now U.S. Pat. No. 8,429,118 entitled Embedding and Retrieving Data in an Application File Format, which is assigned to the assignee of the present application, and hereby incorporated by reference.

**BACKGROUND**

Embedding and retrieving data in an application file format is an extensible process for storing data in a work file without the application needing to understand the content and/or the format of the data. In some situations, users have no way to move and/or access data from an external data source. For example, data may be stored in an online database and inaccessible while working offline. If manipulating the data comprises complex, multi-dimensional queries such as Online Analytical Processing (OLAP), large amounts of data may need to be stored and/or managed separately from other working data. This conventional strategy may cause problems as the management of separate data files may cause distribution and synchronization issues, especially if the data is part of a collaboration project. Furthermore, some users may not have the skills or experience to create multi-dimensional objects on their own, and may wish to use familiar applications for sharing and manipulating such objects rather than relying on other users with the necessary skills to create them.

**SUMMARY**

Embedding and retrieving data in an application file format may be provided. This Summary is provided to introduce a selection of concepts in a simplified form that are further described below in the Detailed Description. This Summary is not intended to identify key features or essential features of the claimed subject matter. Nor is this Summary intended to be used to limit the claimed subject matter's scope.

Third party data embedding may be provided. Data associated with a third party provider may be saved in a native application save file. If a save file opened by the application is determined to comprise third party data, the application may determine whether an appropriate data provider is available. The application may connect to the data provider and provide on-demand access to the third party data upon request from a user and/or another program.

Both the foregoing general description and the following detailed description provide examples and are explanatory only. Accordingly, the foregoing general description and the following detailed description should not be considered to be restrictive. Further, features or variations may be provided in addition to those set forth herein. For example, embodiments may be directed to various feature combinations and sub-combinations described in the detailed description.

**BRIEF DESCRIPTION OF THE DRAWINGS**

The accompanying drawings, which are incorporated in and constitute a part of this disclosure, illustrate various embodiments of the present invention. In the drawings:

## 2

FIG. 1 is a block diagram of an operating environment;

FIG. 2 is a block diagram illustrating a save file;

FIG. 3 is a flow chart of a method for providing access to third party data; and

FIG. 4 is a block diagram of a system including a computing device.

**DETAILED DESCRIPTION**

The following detailed description refers to the accompanying drawings. Wherever possible, the same reference numbers are used in the drawings and the following description to refer to the same or similar elements. While embodiments of the invention may be described, modifications, adaptations, and other implementations are possible. For example, substitutions, additions, or modifications may be made to the elements illustrated in the drawings, and the methods described herein may be modified by substituting, reordering, or adding stages to the disclosed methods. Accordingly, the following detailed description does not limit the invention. Instead, the proper scope of the invention is defined by the appended claims.

Embedding of third party data in an application file may be provided. Software applications may use a native file format for saving data. For some applications, the native file format may not support types and/or amounts of data that a user may wish to view, edit, and/or modify within the application. For example, a spreadsheet application may be limited to storing up to one million rows of data in a single workbook save file, but a user may wish to interact with a database comprising tens of millions of data rows. The user may also wish to perform operations on the data that is not available within the application, such as producing reports based on an Online Analytical Processing (OLAP) cube within the spreadsheet application. A data provider such as an Object Linking and Embedding Database (OLEDB) interface may connect with the application to provide this interaction functionality.

Consistent with embodiments of the invention, the application may access a data provider that may provide support for loading and manipulating the third party data. The application may create a segment within its save file and allow the data provider to write its data directly to the segment of the save file. The file may be shared between different instances of the application, such as a second installation of the spreadsheet application on another user's computer, and opened as a native application file. On opening the file comprising the third party data, the application may determine whether a data provider is available to handle the data and use the data provider to allow access to the third party data, immediately and/or upon a user's attempt to access the data.

Further consistent with embodiments of the invention, the third party data may not be loaded until the user requests access to it. For example, the spreadsheet workbook may comprise a graph created using the third party data. The graph may be displayed as a picture to the user without needing to access the referenced third party data. If the user tries to modify the graph, the application may then utilize the data provider to load the third party data into memory and display the data to the user for interaction. This data loading may be performed asynchronously; that is, the user may be able to continue interacting with the application while the data provider is loading the third party data.

The ability to store third party data in the application file may enable users to store third party data without the application having to understand the format or contents of

## 3

the data. Because the data is stored within the application file, that file may be distributed and used like any other application file, without losing the custom data and without needing a network connection to access that data. Application files containing custom third party data may remain responsive because they may be loaded on demand and asynchronously.

FIG. 1 is a block diagram of an operating environment 100 for embedding and retrieving data in an application file format. Operating environment 100 may comprise an application 110 associated with a save file 120. Save file 120 may comprise a native format associated with application 100 and/or a standard file format associated with a plurality of applications. For example, the Office Open XML standard is a file format for representing application data such as spreadsheets, charts, presentations, and word processing documents. The Open XML standard has been propagated as International Standard specification ISO/IEC 29500:2008. Save file 120 may comprise a plurality of segments, such as a native application data segment 125 and a third party data segment 130. Segments may further comprise divisions based on data type, such as an XML data segment. Consistent with embodiments of the invention, save file 120 may comprise a single file divided into segments for storing the both native and third party data and/or a compressed archive including a primary index file and a plurality of sub files. Consistent with embodiments of the invention, the primary index file may comprise links and/or location indices for any and/or all of the sub files.

Operating environment 100 may further comprise a third party application 140, a data provider 150, and a service provider 160. Third party application 140 may comprise, for example, a data manipulation application operative to create and/or manage a data cube, such as an OLAP cube. Data provider 150 may comprise an application and/or utility that may read, process, and/or translate data associated with third party application 140 and service provider 160 may comprise additional functionality available to operating environment 100. For example, data provider 150 may comprise an OLEDB provider operative to read the OLAP cube and forward data and/or queries to a database engine comprising service provider 160. Data provider 150 may also provide data to application 110, such as by providing the OLAP cube data to a spreadsheet application for viewing, modification, and/or other interactions. A user may thus exploit data provider 150 to leverage the data format of third party application 140 and the functional capabilities of application 110. To the user, the third party data may appear as a normal data file of the native type associated with application 110. When application 110 opens a file comprising third party data, application 110 may provide data provider 150 with a Uniform Resource Locator (URL) of the file. Data provider 150 may forward this URL to service provider 160 that may open the native file, extract the third party data, and provide the third party data to application 110. Consistent with embodiments of the invention, application 110 may open a file in its native format and detect the presence of third party data. Application 110 may then pass a pointer to the third party data to data provider 150 via a generic interface; that is, application 110 may use the same interface regardless of the format or destination provider associated with the third party data. Data provider 150 may forward the third party data to service provider 160 that knows how to read the third party data using the generic interface. Service provider 160 may then extract the third party data and return it to application 110 for display.

## 4

FIG. 2 is a block diagram illustrating a save file 200 consistent with embodiments of the invention. Other embodiments may comprise other formats, such as a single file comprising a segment for storing the third party data. Save file 200 may comprise a third party data folder 210 for storing third party data. Third party data folder 210 may comprise two associated files: a data file 220 and a property file 230. Third party data folder 210 may further comprise additional data files and companion property files (not shown). Data file 220 may comprise the actual data for third party data 130 and property file 230 may comprise properties associated with third party data 130. Third party data folder 210 may further comprise a relationship folder 240 comprising a relationship file 250 associated with data file 220. Relationship file 250 may specify the relationship between data file 220 and property file 230.

The format of the data in data file 220 may not be understood by application 110. When application 110 reads and writes data file 220, it may treat the contents as a chunk of data of a specified size. When application 110 opens a file containing a third party data segment, such as save file 200, application 110 may not load third party data 130 into memory immediately. Application 110 may only read and write to/from save file 220 when saving an unloaded third party data part to a new file.

Property file 230 may comprise a list of properties for associated data file 220. For example, property file 230 may comprise a unique identifier of the associated third party data part, a location for an associated data provider, and/or a list of alternative data providers able to process third party data 130. The unique identifier may comprise, for example, binary data, a uniform resource name (URN), a uniform resource locator (URL), a uniform resource identifier (URI), and/or a numeric and/or alphanumeric identifier string. This unique identifier may be created and/or managed by third party application 140 and/or data provider 150, and application 110 may use the unique identifier to determine which data file is being requested by data provider 150. The identifier may be specified by an identity attribute of an XML element and may be qualified by a namespace. An example of property file 230 may comprise the following XML:

---

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?>
<ds:datastoreItem ds:itemID="Microsoft.SqlServer.AnalysisServices.1"
xmlns:ds="http://schemas.openxmlformats.org/officeDocument/2006/
customData">
  <ds:schemaRefs />
</ds:datastoreItem>
```

---

Relationship file 240 may specify the relationship between data file 220 and property file 230. The <Relationship> element may specify a relationship id (the Id attribute); a relationship type (the Type attribute); and the data file that the corresponding property file applies to (the Target attribute). The following XML illustrates an example relationship file 240. In this example, relationship file 240 specifies that the property file applies to the item1.data file.

---

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<Relationships
xmlns="http://schemas.openxmlformats.org/package/2006/relationships">
  <Relationship Id="rId1"
Type="http://schemas.openxmlformats.org/officeDocument/2006/
relationships/customDataProps" Target="item1.data" />
</Relationships>
```

---

## 5

Save file **200** may comprise a connection string for aiding in connecting the third party data with service provider **160**. Application **110** may not need to parse or understand the connection string, but may pass it to data provider **150** when required to do so. Third party application **140** may be responsible for properly creating the connection string and associating it with the third party data. When application **110** accesses an instance of data provider **150**, it may query data provider **150** to determine whether it supports third party data. After establishing that data provider **150** supports the third party data, application **110** may pass, for example, a full file name and path of save file **200**. Application **110** may then request the URN of the third party data from data provider **150**, locate the data file of the specified third party data (i.e., data file **220**), and create a read/write I/O stream for data file **220**. For example, application **110** may supply data provider **150** with a persistent pointer through which data provider **150** may read from and write to the third party data.

Additionally, application **110** may supply data provider **150** with a location where data provider **150** may store temporary files. Application **110** may also pass a last modified date of save file **200** and/or a user security token needed to access save file **200**. Application **110** may identify any third party data parts associated with save file **200** without interacting with data provider **150**. This may allow application **110** to cope with a scenario where a relationship link to a third party data part may be deleted from save file **200** before application **110** connects to data provider **150**. When there are no links referencing a third party data part, the data may be deleted from save file **200**. A reference link may comprise an XML segment, such as the following, comprising a URN of third party data **130** to which the link refers.

---

```
<connection id="1" emmbeddedDataId="Company.DBServer-
ServiceProvider.1" odcFile="c:\users\anyone\documents\
my data sources\Example.odc" keepAlive="1" name="Example"
description="" type="5" refreshedVersion="0"
new="1" background="1">
```

---

Application **110** may support connecting to data provider **150** asynchronously. For example, data provider **150** may load the custom, third party data during the connection phase. Connecting asynchronously may enable application **110** to remain responsive throughout the connection process and may enable the user to cancel the connection process if it is taking too long. Data provider **110** may also return values to application **110** that may indicate how much of the work data provider **110** has loaded and how much work it still has to do. This may enable application **110** to display a progress bar.

A user may use third party application **140** to create a third party data part. Third party application **140** may first create a connection between third party data **130** and service provider **160** and may configure a connection string comprising an identifier associated with data provider **150** and/or a URN associated with third party data **130**. Application **110** may then try to connect to third party data **130** as if third party data **130** already exists. When the connection workflow reaches the point where application **110** tries to locate third party data **130** for a specified URN, application **110** may discover that third party data **130** does not exist in file **120**. Application **110** may then create third party data folder **210** (if it does not already exist) and may create data file **220**, property file **230** and relationship file **250** associated with third party data **130**.

## 6

When application **110** saves file **120**, it may save the data to a new file and then delete the original. During the save process, third party data **130** may not have been loaded; application **110** may copy third party data **130** to the new file without establishing a connection to data provider **150**. For third party data parts that have been connected to, application **110** may check an attribute associated with a pointer to the connection stream to determine whether the data has changed. If so, application **110** may request data provider **150** to serialize the updated data into the new file.

If a user requests to delete the connection to third party data **130**, application **110** may locate and delete all objects that are using the connection. Application **110** may further determine whether third party data **130** is associated with any other files used by application **110**. If third party data **130** is not associated with any other files, application **110** may delete third party data **130** as well. Deleting third party data **130** may comprise deleting file **120** comprising third party data **130**, deleting property file **230**, and/or deleting relationship file **250**. If there is no more third party data associated with file **120**, then application **110** may also delete third party data folder **210**.

FIG. **3** is a flow chart setting forth the general stages involved in a method **300** consistent with an embodiment of the invention for embedding and retrieving third party data in an application's native file format. Method **300** may be implemented using a computing device **400** as described in more detail below with respect to FIG. **4**. Ways to implement the stages of method **300** will be described in greater detail below. Method **300** may begin at starting block **305** and proceed to stage **310** where computing device **400** may open a file associated with an application. For example, a spreadsheet application may open a workbook file.

From stage **310**, method **300** may advance to stage **315** where computing device **400** may determine whether the file comprises at least one third party data segment. For example, the third party data segment may comprise an OLAP cube stored as binary data.

If, at stage **315**, computing device **400** determines that the file does not comprise a third party data segment, method **300** may end at stage **360** and computing device **400** may open the native application file as normal. Otherwise, method **300** may advance to stage **320** where computing device **400** may determine whether a data provider associated with the third party data segment is available. For example, if the file is opened on the same computer, then the same data provider used to store the third party data is likely to be available, but if the file is transferred to another computer, the data provider associated with the third party data may not be available. Consistent with embodiments of the invention, property file **230** may identify the data provider that originally stored the third party data and/or other data providers that may be able to interface with the third party data.

If, at stage **320**, computing device **400** determines that no data provider is available, method **300** may end at stage **360** and computing device **400** may open the native application file as normal. Otherwise, method **300** may advance to stage **325** where computing device **400** may establish a connection between the application and the data provider. For example, application **110** may connect to data provider **150** according to a connection string stored in data file **220** and/or property file **230**. Application **110** may also provide a security token, if needed, to data provider **150**.

From stage **325**, method **300** may advance to stage **330** where computing device **400** may receive a request from a user to access at least one third party data segment. For

example, the user may attempt to interact with third party data displayed in application 110, such as modifying a chart based on the third party data.

From stage 330, method 300 may advance to stage 335 where computing device 400 may open a file stream interface to data provider 150 allowing data provider 150 to read and/or write to a save file location associated with application 110. This may allow data provider to read the third party data and may allow application 110 to interoperate with the third party data. Data provider 150 may expose the third party data to application 110 using a data interface supported by application 110.

Method 300 may then advance to stage 340 where computing device 400 may display the third party data. For example, application 110 may receive the data from data provider 150 and display it to the user. Method 300 may then advance to stage 345 where computing device 400 may receive a modification to the third party data from the user. For example, a user may update business insight data received from third party application 140 and use it to create and/or update a chart using functionality associated with application 110.

From stage 345, method 300 may advance to stage 350 where computing device 400 may provide the data modification to the data provider. For example, application 110 may save the file comprising the third party data and may inform data provider 150 that the data has changed and needs to be saved. Method 300 may then advance to stage 355 where computing device 400 may update the third party data segment stored in the file. For example, data provider 150 may use the file stream interface to write the updated data to a segment of the save file associated with application 110. Consistent with embodiments of the invention, if the third party data has not been changed, method 300 may skip stage 355. Method 300 may then end at stage 360.

An embodiment consistent with the invention may comprise a system for embedding data in a native application file. The system may comprise a memory storage and a processing unit coupled to the memory storage. The processing unit may be operative to establish a connection interface between an application and a data provider allowing the data provider to write data to the application. The processing unit may be further operative to receive data from the data provider and store the data in a file associated with a native format of the application. The data may be collected, by the data provider and/or a third party application, from a plurality of sources such as multiple databases, servers, or other application data. The processor may be further operative to expose the third party data to a user, receive modifications to the data, and save the modifications via the data provider.

Another embodiment consistent with the invention may comprise a system for accessing third party data in an application file. The system may comprise a memory storage and a processing unit coupled to the memory storage. The processing unit may be operative to open a file comprising a third party data segment associated with an application, determine whether a data provider associated with the third party data segment is available, and establish a connection between the application and the data provider. The file may comprise a primary index file comprising a location index, such as a URN, identifying a sub-file comprising the third party data segment. The processing unit may be further operative to provide a write-access interface to the data provider allowing the data provider to write data to the file associated with the application. Consistent with embodi-

ments of the invention, the data provider may be operative to connect with and provide data interactions with a plurality of other applications.

Yet another embodiment consistent with the invention may comprise a system for providing access to third party data. The system may comprise a memory storage and a processing unit coupled to the memory storage. The processing unit may be operative to open a file associated with an application, determine whether the file comprises a third party data segment, determine whether a data provider associated with the at least one third party data segment is available, and establish a connection between the application and the data provider. The processing unit may be further operative to receive a request from a user to access the third party data segment, provide a read-write interface between the file and the data provider, and display at least a portion of the third party data segment as defined by the data provider. The processing unit may then be operative to receive a modification to the third party data segment from the user, provide the modification to the third party data segment to the data provider, and receive an update to the third party data segment stored in the file from the data provider.

FIG. 4 is a block diagram of a system including computing device 400. Consistent with an embodiment of the invention, the aforementioned memory storage and processing unit may be implemented in a computing device, such as computing device 400 of FIG. 4. Any suitable combination of hardware, software, or firmware may be used to implement the memory storage and processing unit. For example, the memory storage and processing unit may be implemented with computing device 400 or any of other computing devices 418, in combination with computing device 400. The aforementioned system, device, and processors are examples and other systems, devices, and processors may comprise the aforementioned memory storage and processing unit, consistent with embodiments of the invention. Furthermore, computing device 400 may comprise an operating environment for system 100 as described above. System 100 may operate in other environments and is not limited to computing device 400.

With reference to FIG. 4, a system consistent with an embodiment of the invention may include a computing device, such as computing device 400. In a basic configuration, computing device 400 may include at least one processing unit 402 and a system memory 404. Depending on the configuration and type of computing device, system memory 404 may comprise, but is not limited to, volatile (e.g. random access memory (RAM)), non-volatile (e.g. read-only memory (ROM)), flash memory, or any combination. System memory 404 may include operating system 405, one or more programming modules 406, and may include a user application 110. Operating system 405, for example, may be suitable for controlling computing device 400's operation. Programming modules 406 may include, for example, third party application 140 and/or data provider 150. Furthermore, embodiments of the invention may be practiced in conjunction with a graphics library, other operating systems, or any other application program and is not limited to any particular application or system. This basic configuration is illustrated in FIG. 4 by those components within a dashed line 408.

Computing device 400 may have additional features or functionality. For example, computing device 400 may also include additional data storage devices (removable and/or non-removable) such as, for example, magnetic disks, optical disks, or tape. Such additional storage is illustrated in

FIG. 4 by a removable storage 409 and a non-removable storage 410. Computer storage media may include volatile and nonvolatile, removable and non-removable media implemented in any method or technology for storage of information, such as computer readable instructions, data structures, program modules, or other data. System memory 404, removable storage 409, and non-removable storage 410 are all computer storage media examples (i.e. memory storage.) Computer storage media may include, but is not limited to, RAM, ROM, electrically erasable read-only memory (EEPROM), flash memory or other memory technology, CD-ROM, digital versatile disks (DVD) or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store information and which can be accessed by computing device 400. Any such computer storage media may be part of device 400. Computing device 400 may also have input device(s) 412 such as a keyboard, a mouse, a pen, a sound input device, a touch input device, etc. Output device(s) 414 such as a display, speakers, a printer, etc. may also be included. The aforementioned devices are examples and others may be used.

Computing device 400 may also contain a communication connection 416 that may allow device 400 to communicate with other computing devices 418, such as over a network in a distributed computing environment, for example, an intranet or the Internet. Communication connection 416 is one example of communication media. Communication media may typically be embodied by computer readable instructions, data structures, program modules, or other data in a modulated data signal, such as a carrier wave or other transport mechanism, and includes any information delivery media. The term "modulated data signal" may describe a signal that has one or more characteristics set or changed in such a manner as to encode information in the signal. By way of example, and not limitation, communication media may include wired media such as a wired network or direct-wired connection, and wireless media such as acoustic, radio frequency (RF), infrared, and other wireless media. The term computer readable media as used herein may include both storage media and communication media.

As stated above, a number of program modules and data files may be stored in system memory 404, including operating system 405. While executing on processing unit 402, programming modules 406 (e.g. user application 110) may perform processes including, for example, one or more of method 300's stages as described above. The aforementioned process is an example, and processing unit 402 may perform other processes. Other programming modules that may be used in accordance with embodiments of the present invention may include electronic mail and contacts applications, word processing applications, spreadsheet applications, database applications, slide presentation applications, drawing or computer-aided application programs, etc.

Generally, consistent with embodiments of the invention, program modules may include routines, programs, components, data structures, and other types of structures that may perform particular tasks or that may implement particular abstract data types. Moreover, embodiments of the invention may be practiced with other computer system configurations, including hand-held devices, multiprocessor systems, microprocessor-based or programmable consumer electronics, minicomputers, mainframe computers, and the like. Embodiments of the invention may also be practiced in distributed computing environments where tasks are performed by remote processing devices that are linked through a communications network. In a distributed computing

environment, program modules may be located in both local and remote memory storage devices.

Furthermore, embodiments of the invention may be practiced in an electrical circuit comprising discrete electronic elements, packaged or integrated electronic chips containing logic gates, a circuit utilizing a microprocessor, or on a single chip containing electronic elements or microprocessors. Embodiments of the invention may also be practiced using other technologies capable of performing logical operations such as, for example, AND, OR, and NOT, including but not limited to mechanical, optical, fluidic, and quantum technologies. In addition, embodiments of the invention may be practiced within a general purpose computer or in any other circuits or systems.

Embodiments of the invention, for example, may be implemented as a computer process (method), a computing system, or as an article of manufacture, such as a computer program product or computer readable media. The computer program product may be a computer storage media readable by a computer system and encoding a computer program of instructions for executing a computer process. The computer program product may also be a propagated signal on a carrier readable by a computing system and encoding a computer program of instructions for executing a computer process. Accordingly, the present invention may be embodied in hardware and/or in software (including firmware, resident software, micro-code, etc.). In other words, embodiments of the present invention may take the form of a computer program product on a computer-usable or computer-readable storage medium having computer-usable or computer-readable program code embodied in the medium for use by or in connection with an instruction execution system. A computer-usable or computer-readable medium may be any medium that can contain, store, communicate, propagate, or transport the program for use by or in connection with the instruction execution system, apparatus, or device.

The computer-usable or computer-readable medium may be, for example but not limited to, an electronic, magnetic, optical, electromagnetic, infrared, or semiconductor system, apparatus, device, or propagation medium. More specific computer-readable medium examples (a non-exhaustive list), the computer-readable medium may include the following: an electrical connection having one or more wires, a portable computer diskette, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), an optical fiber, and a portable compact disc read-only memory (CD-ROM). Note that the computer-usable or computer-readable medium could even be paper or another suitable medium upon which the program is printed, as the program can be electronically captured, via, for instance, optical scanning of the paper or other medium, then compiled, interpreted, or otherwise processed in a suitable manner, if necessary, and then stored in a computer memory.

Embodiments of the present invention, for example, are described above with reference to block diagrams and/or operational illustrations of methods, systems, and computer program products according to embodiments of the invention. The functions/acts noted in the blocks may occur out of the order as shown in any flowchart. For example, two blocks shown in succession may in fact be executed substantially concurrently or the blocks may sometimes be executed in the reverse order, depending upon the functionality/acts involved.

While certain embodiments of the invention have been described, other embodiments may exist. Furthermore,

## 11

although embodiments of the present invention have been described as being associated with data stored in memory and other storage mediums, data can also be stored on or read from other types of computer-readable media, such as secondary storage devices, like hard disks, floppy disks, or a CD-ROM, a carrier wave from the Internet, or other forms of RAM or ROM. Further, the disclosed methods' stages may be modified in any manner, including by reordering stages and/or inserting or deleting stages, without departing from the invention.

All rights including copyrights in the code included herein are vested in and the property of the Applicant. The Applicant retains and reserves all rights in the code included herein, and grants permission to reproduce the material only in connection with reproduction of the granted patent and for no other purpose.

While the specification includes examples, the invention's scope is indicated by the following claims. Furthermore, while the specification has been described in language specific to structural features and/or methodological acts, the claims are not limited to the features or acts described above. Rather, the specific features and acts described above are disclosed as example for embodiments of the invention.

What is claimed is:

1. A method for embedding data in an application file, the method comprising:

opening the application file associated with an application, wherein the application file comprises a third party data segment that cannot be interpreted natively by the application;

determining whether a data provider associated with the third party data segment is available;

in response to determining that the data provider is available, establishing a connection between the application and the data provider to interpret the third party data segment; and

displaying, in the application, the application file including the third party data segment via a read-write access interface to the data provider from the application, wherein the read-write access interface is operative to enable the data provider to read and write data to the third party data segment of the application file associated with the application.

2. The method of claim 1, wherein the application file further comprises a native data segment.

3. The method of claim 1, wherein the third party data segment stores third party data.

4. The method of claim 3, further comprising, when it is determined that the data provider is available:

sending a pointer identifying a location of the third party data segment in the application file to the data provider; providing the third party data from the application file via a generic interface;

receiving transformed third party data as data editable by the application; and

displaying the transformed third party data in the application.

5. The method of claim 1, further comprising:

receiving an interpretation from the data provider of third party data stored in the third party data segment to provide the application with a displayable third party data that is displayed by the application as if it were interpreted natively by the application.

6. The method of claim 1, wherein the application file further comprises a compressed archive segment, including

## 12

a primary index file and a plurality of sub-files, wherein the primary index file comprises location indices for each of the sub-files.

7. The method of claim 1, wherein the data provider is operative to provide data interactions with a plurality of applications.

8. The method of claim 1, further comprising:

in response to determining that the data provider is not available, not loading the third party data segment into memory.

9. The method of claim 1, further comprising wherein the data provider is operative to connect to a plurality of applications.

10. The method of claim 1, wherein the connection between the application and the data provider comprises an asynchronous connection.

11. An interface system for enabling third party data within an application, comprising:

a memory storage; and

a processing unit coupled to the memory storage, wherein the processing unit is operative to:

open an application file associated with the application, wherein the application file comprises a third party data segment that cannot be interpreted natively by the application;

determine whether a data provider associated with the third party data segment is available;

in response to determining that the data provider is available, establish a connection between the application and the data provider to interpret the third party data segment; and

display, in the application, the application file including the third party data segment via a read-write access interface to the data provider from the application, wherein the read-write access interface is operative to enable the data provider to read and write data to the third party data segment of the application file associated with the application.

12. The interface system of claim 11, wherein the application file further comprises a native data segment.

13. The interface system of claim 11, when it is determined that the data provider is available and wherein the third party data segment stores third party data that cannot be interpreted natively by the application, the processing unit is further operable to:

send a pointer identifying a location of the third party data in the application file to the data provider;

provide the third party data from the application file via a generic interface;

receive transformed third party data as data editable by the application; and

display the transformed third party data in the application.

14. The interface system of claim 11, further comprising:

receive an interpretation from the data provider of third party data stored in the third party data segment to provide the application with a displayable third party data that is displayed by the application as if it were interpreted natively by the application.

15. The interface system of claim 11, wherein the application file further comprises a compressed archive segment, including a primary index file and a plurality of sub-files, wherein the primary index file comprises location indices for each of the sub-files.

16. The interface system of claim 11, wherein the data provider is operative to provide data interactions with a plurality of applications.

13

17. The interface system of claim 11, further comprising:  
in response to determining that the data provider is not  
available, not loading the third party data segment into  
memory.
18. The interface system of claim 11, further comprising 5  
wherein the data provider is operative to connect to a  
plurality of applications.
19. The interface system of claim 11, wherein the con-  
nection between the application and the data provider com-  
prises an asynchronous connection. 10
20. A computer readable storage device which stores a set  
of instructions which when executed performs a method for  
interfacing with third party data in an application file, the  
method executed by the set of instructions comprising: 15  
opening the application file associated with an applica-  
tion, wherein the application file comprises a third  
party data segment, wherein the third part data segment  
stores third party data that cannot be interpreted  
natively by the application;

14

- determining whether a data provider associated with the  
third party data is available;  
in response to determining that the data provider is  
available, establishing a connection between the appli-  
cation and the data provider;  
sending a pointer identifying a location of the third party  
data in the application file to the data provider;  
providing the third party data from the application file via  
a read-write access interface to the data provider from  
the application, wherein the read-write access interface  
is operative to enable the data provider to read and  
write data to the third party data segment of the  
application file associated with the application; and  
displaying, in the application file, the third party data that  
is read from and written to by the data provider as if it  
were read from and written to natively by the applica-  
tion.
